TITLE: Automation of Thermal and Technological Processes in Iron and Steel Works (Avtomatizatsiya teplovykh i tekhnologicheskikh protsessov na predpriyatiyakh chernoy metallurgii)

PERIODICAL: Stal', 1957, No.11, pp. 1024 - 1027 (USSR).

ABSTRACT: Automatic controlling used in blast furnaces, open-hearth and electric furnaces and rolling mills is outlined. It is pointed out that the progress achieved is to a large extent due to the existence of special organisations grouped in the "Energochermet" Trust: instrument-making factories ("KIP" in Kharkov and "Teplopribor" in Chelyabinsk), the Central Laboratory of Automatics, Central Design Office, etc.

TITLE: Effect of radioactive emission S<sup>35</sup> and Mo<sup>99</sup> on the magnitude of the specific surface of molybdenum disulfide

SOURCE: Radiokhimiya, v. 6, no. 1, 1964, 130-132

TOPIC TAGS: molybdenum disulfide, specific surface, BET method, radioactive radiation, tagged molybdenum disulfide, crystal lattice irregularity, crystallization center formation, specific surface change, sulfur 35, molybdenum 99

ABSTRACT: The effect of radioactive radiation imparted by incorporating S<sup>35</sup> and Mo<sup>99</sup> isotopes, on the specific surface of MoS<sub>2</sub> obtained from a melt was investigated. The specific surface was determined by the BET method by low temperature adsorption of krypton. The specific surface of the radioactive materials differs from that of the non-tagged MoS<sub>2</sub> in that it increases with an

Card 1/3

ACCESSION NR: AP4020063

increase in specific radioactivity. With  $S^{35}$  the increase is fairly regular and the specific surface is tripled with 30 millicurie/gm. radioactivity from about 8 to 24  $m^2/gm.$  With  $Mo^{99}$  the increase is sharper, i.e., almost tripled with 15 millicurie/gm. radiation. (fig. 1). The specific surface of the materials does not change on standing. The difference in specific surface associated with radioactive radiation is apparently caused by the formation of irregularities in the crystal lattice and the creation of additional crystallization centers. TITLE: The use of radioactive tracers to check some analytical methods of separating rhenium and molybdenum

PERIODICAL: Referativnyy zhurnal, Metallurgiya, no. 12, 1962, 15, abstract 12K92 ("Sb. nauchn. tr. Gos. n.-i. in-t tsvetn. met.", 1961, no. 18, 56 - 59)

TEXT: Using radioactive  $\text{Mo}^{99}$  and  $\text{Re}^{186}$  isotopes, the author compares 2 methods of separating low Re amounts from high Mo amounts with the aid of 8-axyquinoline and  $\alpha$ -benzoin oxime. The oxyquinoline method was found to be suitable for Re separation from Mo even if  $\text{Mo} : \text{Re} = 585,000 : 1$ . Most complete Mo separation from Re by chloroform extraction is obtained at pH 4.5. Using  $\text{Re}^{186}$ , it was established that during extraction Re is not transferred completely into the chloroform layer. The  $\alpha$ -benzoin oxime method can not be used to separate low Re from high Mo amounts, due to considerable sorption of Re by a precipitate of Mo  $\alpha$ -benzoin oxime. There are 6 references.

**AUTHORS:** Gulyayeva, Ye.I., Zimakov, I.Ye., and Rudenko, B.I.  
**TITLE:** Extraction of Rhenium from Industrial Solutions using Activated Coal (Izвлечение reniya iz proizvodstvennykh rastvorov pri pomoshchi aktivirovannykh ugley)  
**PERIODICAL:** Tsvetnyye metally, 1959, Nr 5, pp 73-77 (USSR)

**ABSTRACT:** The difficulty in extracting Re from solution is the separation from W and Mo which have similar properties. An ordinary chromatographic method was tried using activated coals types KAD, SK-T, SU-KhU, and MSK-1. The coals were washed with 0.01N  $H_2SO_4$  until they showed acid reaction to methyl orange and then the test solutions were poured through the coal. Afterwards the coal was washed with water and then 1% soda solution to remove the Re, W and Mo. The solutions used are given in Table 1. Radioactive isotopes  $Re^{106}$ ,  $Mo^{99}$ , and  $W^{185}$  were added to the solutions and used to indicate the degree of separation. The best coal was found by testing with the first solution. 0.3, 0.6 and 1.0 g of coal and 4.5 and 7.0 mm diameter columns were tried. Table 2 shows the dynamic exchange capacity under various conditions. It increases with increase in the ratio

Card 1/3

SOV/136-59-5-15/21

Extraction of Rhenium from Industrial Solutions using Activated Coal

height/diameter of column. Fig 2 shows that MSK coal has the greatest absorption. The washing results in Fig 3 show that Re is completely extracted from all the coals so MSK coal was used for further work with the other three solutions. Table 3 shows that the exchange capacity was highest for solution 2 which differed from the other solutions in Mo content and acidity. Fig 4 shows that Re is selectively absorbed by the coal but Mo and W are weakly absorbed. Tests on acidity showed that absorption of W and Mo were practically independent of pH value, but Re absorption increases with inverse pH. Therefore washing was carried out with alkaline solution. Fig 8 shows that Mo and W are washed out before Re. The final solution containing Re has small amounts Mo and W present. Hot soda gave better results than cold soda.

AUTHORS: Zimakov, I. Ye., and Spitsyn, Vikt. I., Academician

TITLE: Effect of radioactive energy on the evaporation rate of a solid

PERIODICAL: Akademiya nauk SSSR. Doklady, v. 141, no. 6, 1961, 1400-1402

TEXT: This is a supplement to a previous paper by the authors on the effect of the radioactive level upon the evaporation rate of  $\text{MoO}_3$  (Ref. 1: Vikt. I. Spitsyn, I. Ye. Zimakov, DAN, 139, No. 3 (1961)), where also the production methods of  $\text{MoO}_3$  with different  $\text{Mo}^{99}$  contents were described. The effect of  $\beta$ -radiator additions such as a)  $\text{Y}^{90}$  ( $E_{\text{max}} = 2.18 \text{ Mev}$ ), b)  $\text{Mo}^{99}$  ( $E_{\text{max}} = 1.23 \text{ Mev}$ ), and c)  $\text{W}^{185}$  ( $E_{\text{max}} = 0.43 \text{ Mev}$ ) as well as the value of their radiant energy were studied. In case a),  $\text{MoO}_3$  powder was soaked with a certain quantity of dissolved radioactive yttrium nitrate (or of not radioactive yttrium nitrate as control), dried, and therefrom

Card 1/3

32432

S/020/61/141/006/018/021

B103/B147

Effect of radioactive energy...

fractions of 0.5 - 0.25 mm were obtained by screening. The specific radioactivity was related to  $\text{MoO}_3$ . c) As admixture, radioactive ammonium tungstate was added to the ammonium molybdate solution. After evaporation of the solution, the residue was moistened with some drops of  $\text{HNO}_3$ .

calcined, and fractions obtained like in case a). The evaporation rate was determined in an electric oven from the change in the length of the quartz spring to which the specimen was fixed. A stream of dry air or nitrogen (flow rate 10 ml/min) was passed through at  $700 \pm 1^\circ\text{C}$ . The changes in the weight of the weighed portions were noted and used for plotting evaporation curves. The evaporation rate (ER) of the preparations containing non-radioactive Y and of those with an initial specific radioactivity of 1.0 and 2.0 millicuries/g is practically constant. From 3 millicuries/g onward, the ER of the non-radioactive specimens differs considerably. The ER of each specimen increases steadily, since the radioactivity of the residual preparation increases owing to  $\text{MoO}_3$

evaporation. In the case of c) this difference sets in at 5 millicuries/g. No radioactive products were found in the sublimate. The dependence of the ER of  $\text{MoO}_3$  on its specific radioactivity does not differ from that

Card 2/3

32432

Effect of radioactive energy...

S/020/61/141/006/018/021  
B103/B147

described in Ref. 1. Thus, it has been found that the ER of  $\text{MoO}_3$  depends not only on the radioactivity level of the preparation, but also on the radiant energy of the radioactive addition. The ER of  $\text{MoO}_3$  is affected not only by the radiation of a) but also by the radiation of the foreign radioactive inclusions in the solid phase. There are 4 figures and 1 Soviet reference.

TITLE:

The Determination of the Solubility of Barium-tungstate by Means of the Radioactive Tungsten Isotope -  $^{185}$  (Opredeleniye rastvorimosti vol'framata bariya s pomoshch'yu radioaktivnogo izotopa vol'frama -  $^{185}$ )

PERIODICAL:

Zavodskaya Laboratoriya, 1959, Vol 25, Nr 2, pp 133-134 (USSR)

ABSTRACT:

Slightly soluble barium tungstate (I) is used in separating tungsten from rhenium in the determination of the rhenium content in tungsten concentrates. In the present case the solubility of (I) was determined in water. The indicator used ( $^{185}\text{W}$ ) possesses a  $\beta$ -radiation with an energy of 0.430 Mev and a half-life of 73.2 days. Tests were carried out in a vessel with a spiral agitator. The activity of the dry residue was measured by means of the counter MST-17 and the solubility calculated on the basis of an equation (Table). The curve representing the solubility as a function of the temperature (Fig 1) shows that (I) is the least soluble at  $10^{\circ}\text{C}$  and that the solubility increases moderately at temperatures below  $10^{\circ}\text{C}$ . The dependence of the solubility

Card 1/2

The Determination of the Solubility of Barium-  
tungstate by Means of the Radioactive Tungsten Isotope - 185

SOV/32-25-2-2/78

on the pH value was studied with a pH meter of the LP-5 type with a glass electrode at 20° in hydrochloric acid and soda lye. The investigation results show (Fig 2) that the precipitation of (I) is most complete at a pH value of 6-7. There are 2 figures and 1 table.

TITLE: Effect of radioactivity of molybdenum anhydride on the rate of its evaporation

PERIODICAL: Akademiya nauk SSSR. Doklady, v. 139, no. 3, 1961, 654-657

TEXT: For their studies the authors used preparations of molybdenum anhydride containing  $\text{Mo}^{99}$  (half-life period 68.3 hr) which emits  $\beta$ -particles of high energy ( $E_{\text{max}} = 1.23$  Mev, 85 %). The specimens had a specific activity of 1.0-28.0 millicuries/g. A mixture of calculated amounts of highly active and inactive  $\text{MoO}_3$  was converted with ammonia into ammonium molybdate; the solution was evaporated and annealed with small amounts of nitric acid to prevent the reduction of hexavalent Mo through ammonia. The  $\text{MoO}_3$  obtained was mixed with small amounts of  $\text{Nb}_2\text{O}_5$  and  $\text{ZrO}_2$ , and sublimated at  $350^\circ\text{C}$  in a weak air current for purification from radiochemical admixtures. The particle size was 0.25-0.5 mm.

Card 1/5

25725

S/020/61/139/003/024/025  
B127/B206

Effect of radioactivity of molybdenum...

Working method: A dry current of air was conducted through the layer of molybdenum powder at a rate of 8 ml/min and 700°C temperature. Every 15 min, the quartz crucible was removed, cooled, weighed, and again suspended in the tube. Table 1 shows the experimental results. The following dependence between rate of evaporation and radioactivity was established: At a specific activity of  $\text{MoO}_3$  of 2.5-3 millicuries/g, the rate of evaporation equals the inactive specimen. At a specific activity of 2.5-4 millicuries/g, a drop of the rate of evaporation was established. At 4-9 millicuries/g, a fast increase of the rate of evaporation was observed, which was retarded at a further increase of the specific activity. An increase of the electric charge on the surface was observed on the basis of  $\beta$ -particle emission. It probably also had an effect on the rate of evaporation, which becomes obvious in an interaction between the surface of the hard substances and the gaseous molecules. In the  $\text{MoO}_3$  molecule, the Mo is surrounded by three negatively charged oxygen atoms. The positive charge of the solid  $\text{MoO}_3$  prevents, therefore, transition into the vapor phase. The following experiment was made for explanation: In a crucible with radioactive  $\text{MoO}_3$ , an earthed platinum

Card 2/5

Effect of radioactivity of molybdenum...

25725

S/020/61/139/003/024/025  
B127/B206

wire was brought directly to the specimen. The results in Figs. 3 and 4 confirm the assumption that the electric charge causes the retardation of the rate of evaporation at 2.5-4 millicuries/g. The increase of the rate of evaporation of  $\text{MoO}_3$  above 4-5 millicuries/g depends on the radiation effects in the gaseous phase. A strong flow of  $\beta$ -particles ionizes the evaporated molecules to  $\text{MoO}_3^+$  which repel themselves from the surface. The surface of the crystals is changed through radioactive radiation. The electron-microscopic pictures showed a surface for  $\text{MoO}_3$  entirely different from that for  $\text{MoO}_3$  which is full of irregularities, elevations, and depressions, the size of which depends on the strength of the specific radioactivity. It is also pointed out that the rate of evaporation begins to increase only at doses  $> 10^{16}$  ev/g·sec in the case of an external irradiation of  $\text{MoO}_3$  by an electron current of 800 kev. There are 4 figures, 1 table, and 14 Soviet-bloc references...

TITLE: Electron-microscopic examination of the effect of radio-  
active radiation of solids on the structure of their surface

PERIODICAL: Akademiya nauk SSSR. Doklady, v. 139, no. 5, 1961, 1163-1165

TEXT: The crystal lattice of solids is disturbed by the ionizing action  
of their own radioactive radiation and the appearing recoil atoms, which  
also changes their surface structure. According to the authors, all this  
may be one of the causes of the effect exerted on physicochemical  
properties of solids by their own radiation (sorptive power, solubility  
in water, kinetics of heterogeneous processes of isotopic exchange,  
catalysis, etc.). The authors made electron-microscopic studies of the  
surface structure of radioactive samples of  $K_2SO_4$ ,  $MgSO_4$ ,  $BaSO_4$  and  
 $MoO_3$  which had been used previously to study adsorption, catalysis, and  
isotopic exchange. Except for  $BaSO_4$ , the pictures were obtained by

replication, and for  $\text{BaSO}_4$  the method of double replicas (silver-quartz replicas) was used.  $\text{K}_2\text{SO}_4$ ,  $\text{MgSO}_4$ , and  $\text{MoO}_3$  were applied to a collodion film in the form of a fine powder. A 200 - 300 Å thick quartz layer was sputtered onto it in vacuo. After dissolution of collodion in amyl acetate, the quartz replica were rinsed in distilled water in the case of  $\text{K}_2\text{SO}_4$  and  $\text{MgSO}_4$ , and in dilute alcohol in the case of  $\text{MoO}_3$ . Radioactive samples of K and Mg were obtained by adding small amounts of  $\text{Na}_2\text{SO}_4$  containing  $\text{S}^{35}$ .  $\text{BaSO}_4$  precipitates were isolated by a method previously described by Vikt. I. Spitsyn, V. V. Gromov (DAN, 121, 722 (1958); Radiokhimiya, 1, 181 (1959)). Radioactive  $\text{MoO}_3$  was obtained by adding an  $\text{Mo}^{99}$  containing sample to ordinary  $\text{MoO}_3$  in order to attain the necessary specific radioactivity. The mixture was converted to ammonium molybdate by treating it with aqueous ammonia; it decomposed when heated. The resultant  $\text{MoO}_3$  was sublimed at 850°C. When comparing the pictures (magnification: 12,000 times) [Abstracter's note: Not reproducible] the

authors found the following differences in the crystal surface of a) radioactive and b) non-radioactive samples: 1) The surface of b) is comparatively smooth, that of a) highly pitted. The crystal surface of  $\text{BaSO}_4$  is changed to a high extent by incorporation of small radium amounts.  $\text{K}_2\text{SO}_4$ ,  $\text{BaSO}_4$ , and  $\text{MoO}_3$  also show some changes in their surface structure after an external irradiation with 800-kev electrons. Although the dose was much higher in this case, the changes were less pronounced than those caused by radioactive radiation. The above surface defects appear rather regularly over the whole length of the crystal of the radioactive substance. The deep cavities observed in samples irradiated with neutrons were absent. The surface changes resemble those observed in metal etched by an ion beam. The authors further conclude from the comparison of the photographs that the surface defects of the radioactive samples develop already during the separation of the solid phase from the solution or from the gas. They assume that the radiation of electrons or other charged particles during the crystallization of solid substances gives rise to a great number of new active centers (seed crystals). The particle-size distribution on separation of radioactive salts from

TITLE: The Method of Multiple Radioactive Dilution for Determining Trace Amounts in Mixtures (Metod mnogokratnogo radioaktivnogo razbavleniya dlya opredeleniya malykh primesey)

PERIODICAL: Zavodskaya Laboratoriya, 1958, Vol. 24, Nr 3, pp. 922-925 (USSR)

ABSTRACT: Previous methods of using radioactive dilution for determining trace amounts in mixtures have had a certain disadvantage. The specific activity and the amount of the isolated substance have had to be determined by an analytical method. In this paper a method is described which eliminates this disadvantage. This determination involves adding two different amounts  $m_1$  and  $m_2$  of the radioactive isotope of the substance  $x$  being determined to two similar solutions of this substance. By withdrawing equal amounts of substance  $y$  the concentration of the substance  $x$  to be analysed can be calculated according to the activity. The paper gives the formula for calculating the concentration, and gives several other equations as well. If the weighed amount of the sample to be analysed and the specific activity of the preparation are increased the ad-

for Determining Trace Amounts in Mixtures

SOV/32-24-8-2/43

mixture can be determined in the order of magnitude of  $10^{-5}$  to  $10^{-7}$  % with an accuracy of about 10 %. A method of determining trace amounts of antimony in lead was worked out. The main problem here was to find a way by which small and equal amounts of the substance to be analysed could be separated from solutions of different concentrations. The most suitable method found for this purpose was extraction of the antimony-methylviolet complex compound with toluene. The optimal acidity of the antimony solution was found to be 1:9 in HCl. A procedure as well as tables of results obtained are given.

There are 2 tables.

TITLE: Effect of the radioactivity of molybdenum trioxide on the  
change of its specific surface

PERIODICAL: Akademiya nauk SSSR. Doklady, v. 148, no. 4, 1963,  
884-885

TEXT: The specific surface was studied in  $\text{MoO}_3$  samples containing  
different quantities of  $\text{Mo}^{99}$  ( $T_{1/2} = 68.3$  hr,  $E(\beta)_{\text{max}} = 1.23$  Mev). A  
mixture of radioactive and non-radioactive  $\text{MoO}_3$  was converted by  $\text{NH}_4\text{OH}$   
to ammonium molybdate. The solution was evaporated and the residue  
calcined with addition of  $\text{HNO}_3$  to prevent reduction of sexivalent Mo by  
 $\text{NH}_3$ . The  $\text{MoO}_3$  recovered was mixed with small quantities of  $\text{Nb}_2\text{O}_5$  and  
 $\text{ZrO}_2$  and sublimated at  $850^\circ\text{C}$ . The surfaces were measured in samples of

Card 1/2

B144/B101

0.5 - 0.25 mm granulation. The external specific surface (without blind pores) was measured by filtering rarefied air through the sample and determining the resistance. At radioactivities up to  $\approx 10$  mci/g, these surfaces decreased slightly, whereas with higher mci values they increased. The total surface was determined by the BET method with adsorption of krypton (area occupied by the Kr molecules:  $19.5 \text{ \AA}^2$ ). Additions of radioactive  $\text{MoO}_3$  up to 10 mci reduced the total specific surface (maximum 30%), while higher additions increased it. The absolute values obtained by the two methods were rather similar, which indicates only a small number of blind pores. Based on a previous study (DAN, 139, 654 (1961)), the reduction of the specific surface with low radioactivities is attributed to the reduction of the evaporation rate. Higher radioactivity entails higher evaporation rates and formation of dendrites owing to the effect of  $\beta$ -particles. There are 2 figures.

ABSTRACT: In the last 5 years the Institute of Physical Chemistry, Academy of Sciences SSSR (Institut fizicheskoy khimii Akademii nauk SSSR) gathered numerous data concerning the influence of radioactive radiations of solids on their physico-chemical properties, in particular the production of nonuniform crystals. The present article contains further data collected during the study of radioactive crystalline powders of barium tungstate, elementary sulfur, molybdenum tri- and disulfide, all synthesized by crystallization from solutions and gaseous vapors, and precipitation from alloys. The nonradioactive and radioactive samples with differing specific activity were prepared under strictly identical conditions. The samples were studied by measuring their size and their specific surface, and by taking electron-microscopic pictures. The paper describes in considerable detail the

Card 1/2

preparation and analysis of the samples. The results are given in the form of graphs showing the specific surface of crystals as a function of activity and a table summarizing the results of the particle size analysis. Radiation was due to W185, S35, and Mo99 isotopes. The paper concludes with a discussion of the microphotographs. Orig. art. has: 7 figures and 2 tables.

**Catalytic formation of hydrocyanic acid from ammonia and carbon monoxide.** I. V. ZIMARON. *J. Russ. Phys.-Chem. Soc.* 61, 907-1000(1929). The kinetics of the Mäthle and de Godon reaction (C. A. 15, 370) were studied. The expts. were carried out in a glass tube 10 cm. in diam. and 750 mm. long, placed in an elec.-heated furnace and contg. a layer of catalyst over which  $\text{NH}_3$  and CO were passed. The HCN formed was absorbed in U-tubes contg.  $\text{H}_2\text{O}$ .  $\text{ThO}_2$ ,  $\text{ZrO}_2$ ,  $\text{Al}_2\text{O}_3$ ,  $\text{Cr}_2\text{O}_3$ ,  $\text{V}_2\text{O}_5$  and  $\text{UO}_2$  as well as mixts. of these oxides and their ppts. on pumice, brick, and asbestos were tried as catalysts. At the outset,  $\text{ThO}_2$  and  $\text{UO}_2$  show the greatest catalyzing activity, but they also show the quickest drop in activity, namely a 77.3 and a 60.0% decrease after the first 20 min.  $\text{ZrO}_2$  has an insignificant activity at  $400^\circ$ , the temp. at which the other catalysts were used, and  $\text{Al}_2\text{O}_3$  was necessary. After 20 min. it lost only 14-15% of its activity. The drop in catalyst activity is not due to impurities contained in the original gases, but is due to  $\text{CO}_2$  formed from an unavoidable side reaction. The activity of poisoned  $\text{ZrO}_2$ ,  $\text{ThO}_2$  and  $\text{V}_2\text{O}_5$  can be restored by merely leaving them alone for 3 days, but still better by passing an air current over the heated catalyst.  $\text{UO}_2$  never recovers its former activity, and  $\text{Cr}_2\text{O}_3$  only recovers it to a slight extent. Dependence of the reaction velocity on concn. of the gases over the catalyst was tested by changing the CO/ $\text{NH}_3$  ratio by varying the speeds of these gases over the catalyst, as well as by diln. with an inert gas, such as  $\text{H}_2$ . Only an insignificant variation of velocity of HCN formation was found. The main reaction,  $\text{NH}_3 + \text{CO} = \text{HCN} + \text{H}_2\text{O}$ , is usually accompanied by 3 side reactions, one of which is  $2\text{NH}_3 = \text{N}_2 + 3\text{H}_2$ . This disaccn. is particularly large when the catalysts are used in the form of ppts. on porous substances, apparently owing to a peculiarity of  $\text{SO}_2$ . Disaccn. is very small with chemically pure catalysts, and with pure  $\text{ThO}_2$  there is none up to  $(\text{NH})^2$ . The side reaction  $2\text{CO} = \text{C} + \text{CO}_2$  is practically absent with  $\text{ThO}_2$ ,  $\text{ZrO}_2$  and particularly a mixt. of  $\text{ZrO}_2$  and  $\text{V}_2\text{O}_5$ , but with  $\text{UO}_2$  it is considerable, the catalyst becoming covered with C and permanently weakened. Schuffert's results (C. A. 20, 1878) with Ni as catalyst, that CO decomps. can only be prevented when the CO content is less than 10% and the temp. not over  $400^\circ$ , are extended to all the catalysts tried. The reaction  $\text{CO} + \text{H}_2\text{O} = \text{H}_2 + \text{CO}_2$  cannot be avoided. It takes place no matter what catalyst is used and at the expense of either the adventitious moisture or of  $\text{H}_2\text{O}$  formed in the main reaction.  $\text{CO}_2$  thus produced is very harmful. It retards HCN formation and causes the rapid loss of activity of the catalyst, which adsorbs it until the  $\text{CO}_2$  equil. is reached on the surface of the catalyst. BERNARD NELSON

**Behavior of some aqueous solutions in a high-frequency electric field.** P. V. Zimakov. *Compt. rend. acad. sci. U.R.S.S.* 1, 480-2 (in German 480-3) (1954).—In investigating the influence of supersonic radiation on reactions it was noted that when a beaker with a small quantity of solution was placed directly on a metal plate resting on the quartz oscillator in operation, a luminous discharge of various forms occurred in the vapor in the beaker if the solution was at a temp. of about 80°. With the circuit employed, the voltage varied from 3 to 10 kv. and the frequency from 50 to 100 kilohertz. The effect is connected in a way with the supersonic radiation, as it can be obtained simply with the metallic electrodes. The frequency and voltage are of considerable significance for the discharge whose color varies with the material in solution. The discharge takes place between the water vapor, which is necessary for its existence, and the glass walls of the beaker. The discharge occurred with dichloroethanol, dichloroethane,  $\text{AcOH}$ ,  $\text{NaI}$ ,  $\text{NaCl}$ ,  $\text{NH}_4\text{CNS}$  and  $\text{Al}(\text{SO}_4)_3$  as solutes, while no discharge could be obtained with  $\text{H}_2\text{A}$  or with  $\text{KI}$ ,  $\text{AcOH}$  and  $\text{AcOH}$  as solutes. A  $\text{HCl}$  solution gave a discharge only when the frequency of the field was 50 kilohertz. In some cases there were changes in color during discharge. After a 15-min. discharge in a 10% solution of dichloroethanol and the 2-phase system  $\text{H}_2\text{O}$ -dichloroethane, hydrolysis had occurred in each to the extent of 7% and 6%, resp. Iodine was liberated from a solution of  $\text{NaI}$ . H. A. Smith

PROCESSING AND PREPARATION

The determination of zinc in biological material. P. Y. Zumdakov. J. Physiol. (U. S. S. R.) 24, 1992 (in French, 1953) (RUS). - The material to be analyzed is thoroughly dried at temp. below 60°, treated with dil. HCl, allowed to stand several hrs., filtered and the filtrate evapd. to dryness. To the residue is added 1-2 cc. of 1:1 HCl and distd. H<sub>2</sub>O to 15 cc., and H<sub>2</sub>S is passed through the soln. for 15-20 min. After standing 8 hrs the sulfides are filtered and washed thoroughly and the filtrate is evapd. to dryness. To the residue is added 0.1 cc. of glacial HOAc and 14.4 cc. of H<sub>2</sub>O, and H<sub>2</sub>S is passed through the soln. for 20 min. Under these conditions ZnS pptn. and leaves the sulfides of Fe, Ni and Co in soln. After 12-24 hrs 0.25 g. of Al(OH)<sub>3</sub> or talc is added to the soln. with stirring and the soln. is filtered. The ppt. is washed with HOAc, H<sub>2</sub>S soln. and H<sub>2</sub>O until free of Fe, Co and Ni. A final moistening with 2% NH<sub>4</sub>CNS indicates the presence or absence of Fe. The ppt. is treated with 2-4 cc. of 3 N HCl, the soln. is addd. to 10 cc. and 1 cc. of 2% K<sub>4</sub>Fe(CN)<sub>6</sub> is added. The turbidity of the soln. is compared with that of standard solns. conig. 0.02-0.2 mg. of Zn. The results are 10% in error at 0.02 mg. and 2.5-7.5% at 0.04-0.2 mg. of Zn.

Catalytic oxidation of allyl alcohol to acrolein. P. V. Zinchenko and V. A. Pokrovskii. *Compt. rend. acad. sci. U.R.S.S.* 68, 641-3(1945) (in French). -- Allyl alc. (I) was oxidized to acrolein (II) over a Ag catalyst (III) under the same conditions that ethylene is oxidized to ethylene oxide. When 3 vol. % of I in air was passed at 15 l./hr. through a bed of III 100 mm. deep and 30 mm. diam., at a temp. of 200-40°, the conversion of I to II was 70.0% of the theoretical. Under other conditions lower conversions were obtained. W. J. Kirkpatrick

Formation of ethylene oxide from dichloroethane. P. I. Zinakov. *Doklady Akad. Nauk S.S.S.R.* 30, 219-221 (1945). — Passage of  $(Cl_2, Cl_2)$  vapor over Pb oxide deposited on pumice at 120° results only in traces of ethylene oxide (1%). Addn. of steam to the vapor phase (even in small amts.) increases the yield considerably especially if alternate passes are made. The catalyst, however, is very rapidly inactivated. The highest yield (1.25%) was attained with fresh catalyst at 180°. Addn. of 1-10% fresh CuO to the catalyst results in the best yield (0.4%) in the range 120-200°. Above 200° some  $AcCl$  is formed with the mat. yield obtained at 230° (1.6-2%). At 250-300° some  $ClCH_2CH_2OH$  may be detected. Use of H<sub>2</sub> carbonate deposited on pumice results in zero reaction up to 250° (with or without steam) above 250° (max. at 320°) the yields of 1 compare with those obtained from the PbO catalyst used as such. The use of granulated soda lime as the catalyst results in the formation of 1 above 120° (with steam), with a max. yield at 180° (1%); above 200°  $AcCl$  and  $ClCH_2CH_2OH$  begin to form (max. 8% and 0.6%). This catalyst was best for durability, as

0-10 hrs. operation resulted in but a small decrease in conversion. Thus, 1 formation is conditioned by the presence of water. It is believed that the  $\text{PbO}$  catalyst operates at  $120-240^\circ$  by formation of  $\text{ClCH}_2\text{CH}_2\text{OCH}_2\text{Cl}$ , which splits with  $\text{H}_2\text{O}$  to  $\text{HOCH}_2\text{CH}_2\text{OH}$  and  $\text{ClCH}_2\text{CH}_2\text{OH}$ , and the latter yields 1,3,5 reaction with  $\text{PbO}$ . Acid formation above  $240^\circ$  is an isomerization of 1. The side-line reaction is analogous. The usual hydrolysis of  $(\text{ClCH}_2)_2$  into glycol in the presence of weak bases must be a 2-step hydrolysis going through  $(\text{ClCH}_2)_2$  as intermediate.

Chemical properties of ethylene oxide polymer. P. V. Zimakov and B. V. Ginzburg. *Doklady Akad. Nauk S.S.S.R.* 38, 1661 (1947).—A solid ethylene oxide polymer produced by contact with either dil. NaOH or  $\text{SnCl}_4$ , m. about  $82^\circ$ , was examined. Treatment with  $\text{H}_2$  gave a slump with much heat evolution and no solid deriv. could be obtained; treatment with  $\text{AgNO}_3$  readily pptd. AgBr while KI liberates free  $\text{I}_2$ ; treatment with  $\text{H}_2$  for 48 hrs. gave a liquid product, b.  $100^\circ$ , whose constants are close to those of dioxane. A spot test of the polymer with alc. I gave red crystals which are quite unstable; the product, m.  $82^\circ$ , appears to be  $(\text{C}_2\text{H}_4\text{O})_n$ . Treating with  $\text{SnCl}_4$  yields colorless crystals, m.  $120^\circ$ , which appear to be  $2\text{SnCl}_4 \cdot \text{C}_2\text{H}_4\text{O}$ . Apparently all the reaction products can be formulated like adducts of dioxane at one of the O atoms. G. M. K.

CA  
 Oxidation of allyl alcohol to acrolein. P. V. Zimukhin and V. A. Pokrovskii. Doklady Akad. Nauk S.S.S.R. 43, 143 (1948). The previously proposed scheme (Z. and P., C.I. 40, 1348) of the oxidation on an Ag catalyst,  $\text{CH}_2=\text{CHCH}_2\text{OH}$  (I)  $\xrightarrow{\text{O}_2}$   $\text{OCH}_2\text{CHCH}_2\text{OH}$  (II).

—(II)  $\text{CH}_2=\text{CHCHO}$  (III), was tested by a qual. reaction for II (neutral urotropine + phenolphthalein) and by quant. detn. by the method of Fubotti (C. I. 27, 245). With an Ag powder catalyst column 15 mm. in diam., 300 mm. long, characterized by oxidation of 3 vol. %  $\text{C}_2\text{H}_4$  with air to 50%  $(\text{CH}_3)_2\text{O}$  and 30%  $\text{CO}_2$  and  $\text{H}_2\text{O}$  at 225°.

oxidation of about 30% I with air passed at 10 l./hr., at 150, 170, and 200°, gave yields of 8.20, 47.14, and 83.00% III, no  $\text{CO}_2$ ; at 5 l./hr., 200, 225, and 250°, 0.23, 100.00, and 21.05% III, 0, 0, and 11.4 vol. %  $\text{CO}_2$  in the outg. At 10 l./hr., 175 and 200°, 0.57 and 1.12% II were detected along with 47.14 and 83.00% III; with anisotropic mixt., 1.74 + 11.00.74 vol. %, at 200°, the yield of II reached 13.75%, along with 80.00% III. Evidently,  $\text{H}_2\text{O}$  vapor inhibits further conversion of II to III, in agreement with the proposed scheme. At the same catalyst, II alone with an excess of air is oxidized, at 250°, to the extent of 50%, but mainly to  $\text{CO}_2$  and  $\text{H}_2\text{O}$ , with only small amts. of III. However, mixts. of I and II give high yields of III, e.g., 80% I + 20% II, at 250°, feed rate 1.85 and 5.40 g. mixt./hr., gave, resp., 9.2 and 41.44% II, 72.92 and 80.88% III, as against 0.0% II and 0.30% III with pure I (calcd. for 20% I for comparability). Thus, II appears to be the intermediate product in the oxidation of I; depending on the conditions, it can either be dehydrated to III or hydrated to  $\text{CH}_2(\text{OH})\text{CH}(\text{OH})\text{CH}_2\text{OH}$  as in the expts. of Wagner (Ber. 21, 120, 3347 (1890)).

Participation of polyphenols in peroxidase oxidation of substrates with an imino group. P. V. Zinckey (Acad. Med. Sci., Moscow). *Meditsinskaia 18*, 21 (1951). About peroxidase oxidizes indigo carmine (C.I. 40, 1001<sup>9</sup>). But the plant peroxidase in horse radish, while rapidly oxidizing pyrogallol and guaiacol, can not oxidize indigo carmine. On introducing into the reaction mixt. pyrogallol, guaiacol, or adrenaline, indigo carmine is rapidly oxidized by the horse radish peroxidase. Polyphenols act as intermediate catalysts in the peroxidase oxidation of substrates with imino groups. Apparently blood erythrocytes are capable of rapidly oxidizing substances with imino groups because of the participation of adrenaline as an intermediate catalyst. H. Priestley

A peculiarity in the reaction of ethylene oxide vapor with wood. P. V. Zimakov and V. A. Polkovskii, *Zhur. Prikl. Khim.*, 1954, 27, 649-6. Ordinary wood chips or pieces of cellulose in contact with ethylene oxide vapor at times show development of a brown or black color without any notable change in vol. or without binding large amts. of the oxide. Cellulosic matter pretreated with NaOH reacts with the oxide which diffuses through the cellulonic mass leading to swelling and bursting of structure (in the sense of strength loss), with preservation, however, of all structural details of the original piece. Several photographs are shown, portraying the forms obtained after 2-3 weeks exposures.

Title : Experimental Confirmation of the Presence of Oxonium Form of Ethylene Oxide in Aqueous Solutions

Orig Pub: Zh. fiz. khimii, 1956, 30, No 8, 1904-1905

Abstract: Distortion of valency angles in the molecule of ethylene oxide (I) must increase the affinity of oxygen to the proton and its tendency to conversion to the "oxonium" state. Comparison of blowing with air, at a rate of about 10 liters per hour, of 1.5-1.6% solutions of I, in neutral and in acidified water, at 15-20°, has revealed that from neutral solutions I is driven off completely within 15 minutes, while in acidified solutions up to 15% of the initial amount of I are always retained. In the opinion of the author this is due to a lowering of the vapor tension of I, caused by a solvation, catalyzed by H<sup>+</sup> ions, with formation of the oxonium form of I.

TITLE

On Two Reaction Trends in the Dehydrochlorination of Lower Alkylene Chlorohydrins

(O dvukh napravleniyakh reaktsii degidrokhlorigivaniya nizshikh alkilen-khlorgidrinov, Russian)

PERIODICAL

Doklady Akademii Nauk SSSR, 1957, Vol 115, Nr 2, pp 297-300 (U.S.S.R.)

ABSTRACT

In the year 1959 it will be hundred years since the description by A. Wörz of the reaction mentioned in the title. At that time a new compound, ethylene chlorids, was for the first time produced in an alkaline medium. At present this reaction forms the basis of the commercial production of ethylene by means of chlorine. No note was hitherto taken of the fact that this substance is always obtained with an admixture of 1 - 2 % acetaldehyde, if the reaction is performed with application of milk of lime. These admixtures can develop due to a secondary isomerization reaction of ethylene oxide. In 1939 a French patent was published concerning the formation of considerable quantities of aldehydes (or ketones) beside the  $\alpha$ -oxides on dehydrochlorination of aliphatic chlorohydrins in the environment of "milk of Magnesia". The subject of the patent did not draw the attention of chemists to the two-way reactivity of the simple compound (ethylene chlorohydrin). Some years ago the authors made thorough investigation of the dehydrochlo-

Card 1/3

20-2-28/62

### On Two Reaction Trends in the Dehydrochlorination of Lower Alkylene Chlorohydrins

rationation of ethylenechlorohydrin (denoted EClH in the following) in various media and conditions. The method of the French patent yielded up to 35 % of ethyleneoxide and up to 50 % acetaldehyde. The authors proved that ethylene glycol develops only in the hydration of the primarily-forming ethyleneoxide. Acetaldehyde, as the practically only reaction product (98%), with small admixtures of ethyleneoxide develops in a boiling water suspension of nickeloxide hydrate. This proves that even such a simple compound as EClH, according to the nature of reagents acting on it, distinctly shows two reaction trends. It was interesting to study the particularities of the dehydrochlorination of EClH. In order to make the experimental checking of the above-mentioned assumption (isomerization) easier, the authors used propylenechlorohydrin (=PClH), since this compound exists in 2 ( $\alpha$ - and  $\beta$ -) isomeric forms. Its dehydrochlorination takes place just as easily as that of EClH, but it usually leads to a yield of propylene oxide higher than 85%. The causes of the small yield have not been determined.

Conclusions: 1.) Propion-aldehyde in greater quantities develops on dehydrochlorination of PClH only in suitable media: aqueous suspensions of magnesium- and especially nickel-hydroxide. This is in agreement with the rule governing in the case of EClH. 2.) Propion aldehyde de-

**TITLE:** On the Influence of Temperature on the Process of the  
Hypochlorination of Ethylene (O vliyanii temperatury na  
protsess gipokhlorirovaniya etilena)

**PERIODICAL:** Khimicheskaya promyshlennost', 1958, Nr 4, pp. 210 - 213 (USSR)

**ABSTRACT:** Already Carius (Ref 1) observed the reaction between ethylene  
and hypochlorous acid; however, a technological use of this  
reaction took place only according to the synthesis by  
Gomberg (Ref 2). Greatly differing data exist on the influ-  
ence of the temperature on the course of reaction: Brooks  
(Ref 21) maintained that the hypochlorination is to be car-  
ried out at low temperatures; Zapadinskiy (Ref 3) worked at  
0 - 2°, while Tropsch and Kassler (Ref 10) showed that the  
reaction takes a better course at 40 - 60° than at 0 - 30°.  
According to Demask and Kobe (Ref 15) a rise of temperature  
is to supply a better yield, while Murray (Ref 24) finds 30°  
to be the upper limit. These contradictions made the authors

Card 1/4

SOV / 64-58-4-5/20

On the Influence of Temperature on the Process of the Hypochlorination  
of Ethylene

of this paper assume that the distribution of ethylene and with it its transformation velocity into the solution are dependent on temperature. For this purpose three experimental series were carried out at temperatures of from 0 - 70° and in the case of different acetylene distribution; in the first case a distribution of the gas was arranged by a Schott filter Nr 1, in the second case by openings in the supply tube, and in the third case by means of 1 mm openings. From the results obtained may be seen that in the first series of experiments a rise of temperature leads to an increase in the yield of ethylene chlorohydrin (at 70° up to 90%). The second series showed that under these conditions a change of temperature within a wide range did not exert any influence on the yield and that on the average it amounts to 20%. In the third series of experiments a rise of temperature caused a decrease of the ethylene chlorohydrin yield, so that it was 40% at 90° and 55% at 60°. In order to explain these contradicting results the process of hypochlorination is shown schematically and two basic reactions are assumed - the solution of ethylene and the chlorohydrolysis - which influence the yield. The hydrolysis was already investigated

Card 2/4

SOV/64-58-4-5/20

On the Influence of Temperature on the Process of the Hypochlorination  
of Ethylene

by Yakovkin (Ref 25) who observed an increase in the degree of hydrolysis with the rise of temperature; for the further classification an investigation of the solution kinetics is carried out. It is assumed that for the first experimental series a "kinetic" factor is decisive, while the third experimental results depend on a "diffuse" factor, and the second series has a balancing effect of the temperature on the two mentioned factors; such an independence of the temperature may be observed after all. Based on the results obtained the authors then conclude that a rise of temperature has a favorable effect in the case of a fine distribution of the gases, while in a coarse distribution the temperature factor exerts a negative effect. Thus for obtaining a maximum yield of ethylene chlorohydrin the corresponding conditions must be prepared; the effect of the optimum temperature will be the greater, the greater the velocity of the transition of ethylene from the gaseous phase into the solution - the medium of the reaction. There are 1 figure and 25 references, 10 of which are Soviet.

**PURPOSE:** This collection of articles is intended for scientists and engineers interested in the applications of radioactive materials in science and industry.

organism. The book contains of separate sections concerning various aspects of the chemistry of organic radioactive elements and the processes of radiation effect on matter. These reports discuss presently methods of representing limited nuclear fuel, research in the chemistry of mercury, thorium, uranium, plutonium, and americium, problems related to the synthesis and decay of radioactive wastes, the radiolysis of aqueous solutions and of liquid compounds, the mechanism of polymer chain scission, and the effect of radiation on natural and synthetic polymers. A. J. Presbury edited the present volume. Most of the reports are accompanied by references. Contributions by individual investigators are mentioned in connection to the table of contents.

1974-1975, 1976-1977, 1978-1979, 1980-1981, 1982-1983, 1984-1985, 1986-1987, 1988-1989, 1990-1991, 1992-1993, 1994-1995, 1996-1997, 1998-1999, 2000-2001, 2002-2003, 2004-2005, 2006-2007, 2008-2009, 2010-2011, 2012-2013, 2014-2015, 2016-2017, 2018-2019, 2020-2021, 2022-2023, 2024-2025, 2026-2027, 2028-2029, 2030-2031, 2032-2033, 2034-2035, 2036-2037, 2038-2039, 2040-2041, 2042-2043, 2044-2045, 2046-2047, 2048-2049, 2050-2051, 2052-2053, 2054-2055, 2056-2057, 2058-2059, 2060-2061, 2062-2063, 2064-2065, 2066-2067, 2068-2069, 2070-2071, 2072-2073, 2074-2075, 2076-2077, 2078-2079, 2080-2081, 2082-2083, 2084-2085, 2086-2087, 2088-2089, 2090-2091, 2092-2093, 2094-2095, 2096-2097, 2098-2099, 2100-2101, 2102-2103, 2104-2105, 2106-2107, 2108-2109, 2110-2111, 2112-2113, 2114-2115, 2116-2117, 2118-2119, 2120-2121, 2122-2123, 2124-2125, 2126-2127, 2128-2129, 2130-2131, 2132-2133, 2134-2135, 2136-2137, 2138-2139, 2140-2141, 2142-2143, 2144-2145, 2146-2147, 2148-2149, 2150-2151, 2152-2153, 2154-2155, 2156-2157, 2158-2159, 2160-2161, 2162-2163, 2164-2165, 2166-2167, 2168-2169, 2170-2171, 2172-2173, 2174-2175, 2176-2177, 2178-2179, 2180-2181, 2182-2183, 2184-2185, 2186-2187, 2188-2189, 2190-2191, 2192-2193, 2194-2195, 2196-2197, 2198-2199, 2200-2201, 2202-2203, 2204-2205, 2206-2207, 2208-2209, 2210-2211, 2212-2213, 2214-2215, 2216-2217, 2218-2219, 2220-2221, 2222-2223, 2224-2225, 2226-2227, 2228-2229, 2230-2231, 2232-2233, 2234-2235, 2236-2237, 2238-2239, 2240-2241, 2242-2243, 2244-2245, 2246-2247, 2248-2249, 2250-2251, 2252-2253, 2254-2255, 2256-2257, 2258-2259, 2260-2261, 2262-2263, 2264-2265, 2266-2267, 2268-2269, 2270-2271, 2272-2273, 2274-2275, 2276-2277, 2278-2279, 2280-2281, 2282-2283, 2284-2285, 2286-2287, 2288-2289, 2290-2291, 2292-2293, 2294-2295, 2296-2297, 2298-2299, 2300-2301, 2302-2303, 2304-2305, 2306-2307, 2308-2309, 2310-2311, 2312-2313, 2314-2315, 2316-2317, 2318-2319, 2320-2321, 2322-2323, 2324-2325, 2326-2327, 2328-2329, 2330-2331, 2332-2333, 2334-2335, 2336-2337, 2338-2339, 2340-2341, 2342-2343, 2344-2345, 2346-2347, 2348-2349, 2350-2351, 2352-2353, 2354-2355, 2356-2357, 2358-2359, 2360-2361, 2362-2363, 2364-2365, 2366-2367, 2368-2369, 2370-2371, 2372-2373, 2374-2375, 2376-2377, 2378-2379, 2380-2381, 2382-2383, 2384-2385, 2386-2387, 2388-2389, 2390-2391, 2392-2393, 2394-2395, 2396-2397, 2398-2399, 2400-2401, 2402-2403, 2404-2405, 2406-2407, 2408-2409, 2410-2411, 2412-2413, 2414-2415, 2416-2417, 2418-2419, 2420-2421, 2422-2423, 2424-2425, 2426-2427, 2428-2429, 2430-2431, 2432-2433, 2434-2435, 2436-2437, 2438-2439, 2440-2441, 2442-2443, 2444-2445, 2446-2447, 2448-2449, 2450-2451, 2452-2453, 2454-2455, 2456-2457, 2458-2459, 2460-2461, 2462-2463, 2464-2465, 2466-2467, 2468-2469, 2470-2471, 2472-2473, 2474-2475, 2476-2477, 2478-2479, 2480-2481, 2482-2483, 2484-2485, 2486-2487, 2488-2489, 2490-2491, 2492-2493, 2494-2495, 2496-2497, 2498-2499, 2500-2501, 2502-2503, 2504-2505, 2506-2507, 2508-2509, 2510-2511, 2512-2513, 2514-2515, 2516-2517, 2518-2519, 2520-2521, 2522-2523, 2524-2525, 2526-2527, 2528-2529, 2530-2531, 2532-2533, 2534-2535, 2536-2537, 2538-2539, 2540-2541, 2542-2543, 2544-2545, 2546-2547, 2548-2549, 2550-2551, 2552-2553, 2554-2555, 2556-2557, 2558-2559, 2560-2561, 2562-2563, 2564-2565, 2566-2567, 2568-2569, 2570-2571, 2572-2573, 2574-2575, 2576-2577, 2578-2579, 2580-2581, 2582-2583, 2584-2585, 2586-2587, 2588-2589, 2590-2591, 2592-2593, 2594-2595, 2596-2597, 2598-2599, 2600-2601, 2602-2603, 2604-2605, 2606-2607, 2608-2609, 2610-2611, 2612-2613, 2614-2615, 2616-2617, 2618-2619, 2620-2621, 2622-2623, 2624-2625, 2626-2627, 2628-2629, 2630-2631, 2632-2633, 2634-2635, 2636-2637, 2638-2639, 2640-2641, 2642-2643, 2644-2645, 2646-2647, 2648-2649, 2650-2651, 2652-2653, 2654-2655, 2656-2657, 2658-2659, 2660-2661, 2662-2663, 2664-2665, 2666-2667, 2668-2669, 2670-2671, 2672-2673, 2674-2675, 2676-2677, 2678-2679, 2680-2681, 2682-2683, 2684-2685, 2686-2687, 2688-2689, 2690-2691, 2692-2693, 2694-2695, 2696-2697, 2698-2699, 2700-2701, 2702-2703, 2704-2705, 2706-2707, 2708-2709, 2710-2711, 2712-2713, 2714-2715, 2716-2717, 27

SOV/20-127-2-26/70

TITLE:

The Mechanism of Aldehyde Formation in the Dehydrochlorination of Lower Alkylene Chlorohydrins

PERIODICAL:

Doklady Akademii nauk SSSR, 1959, Vol 127, Nr 2, pp 329-332 (USSR)

ABSTRACT:

The authors proved (Ref 1) that the transformation of the substances last mentioned in the title (ethylene-, propylene chlorohydrin) into a corresponding  $\alpha$ -oxide or aldehyde with good yields depends on the character of the medium in which the reaction proceeds. However, only one isomer, i.e. the  $\beta$ -isomer, of propylene chlorohydrin is transformed into an aldehyde, the  $\alpha$ -isomer is not capable of being transformed (see Scheme). The transformation of the mentioned substances into  $\alpha$ -oxides proceeds in media with a high pH according to the Wurtz-(Vyrts-) reaction (in "milk of lime"). They are transformed especially smoothly into aldehydes in a suspension of nickel hydroxide (Ref 1). The aldehyde yields in "milk of magnesia" are as well considerable (Ref 2). The authors give then considerations with respect to the probable mechanism of such a double-track reactivity of such simple compounds as those mentioned in the title. They have two easily polarisable Cl- and O-atoms which are in a

Card 1/4

Dehydrochlorination of Lower Alkylene Chlorohydrins

SOV/20-127-2-26/70

$\beta$ -position to each other. This favors a maximum reciprocal effect which is often accompanied by the change of the valence stages of both atoms or of one of them. The yperite molecule may serve as an example of such an "activity" of the mentioned  $\beta$ -position of the chlorine atoms and of an easily polarisable sulphur. Its very special toxicity is explained by the slight change in the valence of the mentioned atoms (Ref 3). The activity of the polarisable atoms is also very high in the two mentioned chlorohydrins in consequence of their structural peculiarities. The reactivity is due to this fact. Even an anhydrous ethylene chlorohydrin produces a certain quantity of diethylene-glycol-chlorohydrin in the case of a long storage. An equivalent HCl-quantity becomes liberated in this case (Ref 4). This transformation is caused by the transition of single chlorohydrin molecules into an "active" polar form with changed valence stages of oxygen and chlorine (Ref 5). The Wurtz reaction which leads to the formation of ethylene-oxide proceeds through such an active molecule form of chlorohydrin with oxonium oxygen and with ion chlorine (Ref 6). The propylene oxide is produced from propylene chlorohydrin in the same way. Its two isomers ( $\alpha$  and  $\beta$ )

SOV/20-127-2-26/70

react practically equally. The ethylene-oxide produced in the practical carrying-out of the Wurtz reaction is always accompanied by a small admixture of acetaldehyde (Ref 7). The formation of the latter increases according to reference 8 with decreasing acidity of the medium. At present it must be assumed that the ethylene chlorohydrin molecule may assume a second active "chloronium" form under splitting off of a hydroxyl ion in media not containing an excess of hydroxyls. This must be assumed from the ethylene chlorohydrin formation in the ethylene chlorination in the aqueous medium (Ref 10). Analogous active forms exist for propylene chlorohydrin, however, with a different degree of stability (Ref 11). Nickelous hydroxide  $N(OH)_2$  in suspension is an especially suitable medium, as was already mentioned (Ref 1). It may be assumed that the interaction of ethylene chlorohydrin in the aqueous medium passes in the case of boiling (100°) several stages explained in the scheme. Such alcoholate forms of the nickel compounds are described in reference 13. The considerable tendency of nickel to the formation of a basic chloride is essential, whereas the intermediate compound with

Dehydrochlorination of Lower Alkylene Chlorohydrins

SOV/20-127-2-26/70

alkylene chlorohydrin favors the reconstruction of the molecule of the latter under splitting off of an acetaldehyde. The  $\alpha$ -isomer of propylene chlorohydrin which does not incline to the splitting off of hydroxyl and to the formation of chloronium does not react at all with the nickelous hydroxide (Ref 1). The two chains of the interactions are simultaneous and parallel in the "milk of magnesia" in which the yield of  $\alpha$ -oxides and aldehydes is approximately equal (Ref 14). There are 14 references, 8 of which are Soviet.

TITLE: Radiochemical Chlorination<sup>9</sup> of Benzene\

PERIODICAL: Atomnaya energiya, 1960, Vol. 9, No. 5, pp. 412 - 414

TEXT: The radiative chlorination of benzene was studied under standard conditions in order to study the possibility of using nuclear radiations for the production of hexachlorane. As can be seen from the Table, the different radiations led to the formation of hexachlorocyclohexane (HCCH) characterized by a high content of alpha phase. In addition to data on thermal, chemical (benzene peroxide), and infrared chlorination, the Table gives the following data:

Card 1/3

Radiochemical Chlorination of Benzene

S/089/60/009/005/012/020  
B006/B070

Concentration g chlorine/100g $C_6H_6$	$t^{\circ}C$	$\gamma$ -Isomer %	$\alpha$ -Isomer %	Mean energy ev
Ultraviolet (3650A)14.0	40	11.3	73.8	3 - 5
$\beta$ : (3.48 rad/sec,				
total: $2.4 \cdot 10^4$ rad)14.0	40	10.2	78.5	$0.4 \cdot 10^6$
$\gamma$ : (6.75 rad/sec,				
total: $2.4 \cdot 10^4$ rad)14.0	40	11.8	83.5	$1.2 \cdot 10^6 - 1.3 \cdot 10^6$

On the contrary, the content of  $\alpha$ -isomer on chemical chlorination is only 63.7%. The chlorination was done for pure substance and for solution in  $CCl_4$ . The  $\beta$  source was  $Sr^{90}$ , and the  $\gamma$  source,  $Co^{60}$ . The radiochemical yield of the reaction was 853,000 per 100 ev; it was, however, strongly dependent on the purity of the starting material. If industrially pure benzene is used, the yield is only 130,000. The ultraviolet yielded 9000 molecules per 100 ev. The radiative chlorination rate is proportional to the square of radiation intensity (benzene without solvent). In  $CCl_4$  solution, the rate of reaction is essentially lower.

Card 2/3 .

Radiochemical Chlorination of Benzene

S/089/60/009/005/012/020  
B006/B070

Radiative chlorination of benzene is possible also at low temperatures in solid phase; the total yield increases with decreasing temperature down to  $-80^{\circ}\text{C}$ . Chlorination remains incomplete for temperatures still lower (at  $-120^{\circ}\text{C}$ , the content of tetrachlorocyclohexane reaches 58%). The effect of temperature on the isomeric composition of HCCH was also studied. While the total yield of HCCH has its maximum at  $-80^{\circ}\text{C}$ , the content of  $\alpha$ -isomer decreases from 83.5 to 38% for the fall of temperature from 40 to  $-190^{\circ}\text{C}$ . The yield of  $\gamma$ -isomer also depends on the concentration of chlorine. The formation probabilities of  $\alpha$ -,  $\beta$ -,  $\gamma$ -,  $\delta$ -, and  $\epsilon$ -isomers were calculated to be 27.8, 4.63, 25.0, 26.0, and 16.7%, respectively. There are 4 figures, 1 table, and 3 references: 1 Soviet, 1 German, and 1 Polish.

TITLE:

Use of nuclear radiation energy in the process of the  
polymerization of fluoro-olefines

PERIODICAL:

Referativnyy zhurnal. Khimiya, no. 4, 1962, 557, abstract  
4P24 (Sb. "Radioakt. izotopy i yadern. izlucheniya v nar.  
kh-ve SSSR, v. 1. M.", Gostoptekhzdat, 1961, 219-226)

TEXT: The processes of the separate and combined radiation polymerization  
of tetrafluorethylene and trifluorchlorethylene have been investigated with  
the aim of eliminating some of the deficiencies in existing methods of  
fluoro-olefine polymerization. It has been found that tetrafluorethylene  
and trifluorchlorethylene can easily be polymerized under various  
temperature conditions and mediums with comparatively low radiation  
intensities. The resulting polymers have a high degree of purity. The  
possibility of producing various fluoro-copolymers by radiation is  
demonstrated. Both radiation polymerization and radiation vulcanization  
might be carried out in the case of fluor-containing rubbers. [Abstracter's

TITLE: Some Problems Concerning the Localization of Radioisotopes  
in Connection With the Problem of Their Safe Storage

PERIODICAL: Atomnaya energiya, 1966, Vol. 10, No. 1, pp. 58-63

TEXT: The authors have made a detailed study of the methods used today for the storage of radioactive waste matter, and they now discuss the hazards involved. It must be borne in mind that, in general, radioactive wastes will actually remain on the spot for several centuries, especially if it contains  $\text{Sr}^{90}$ ,  $\text{Cs}^{137}$ , and similar isotopes. First, the authors reject the widespread opinion that fluid radioactive wastes can be safely stored in any container. Apart from corrosion, there may arise considerable overpressure in the gas container. This overpressure results from radioactively evolving gases and might lead to the destruction of the container. Certain radioactive solutions are capable of evolving gas in quantities of up to  $10 \text{ cm}^3/\text{cube per hour}$ . In addition, the activity of the waste matter may heat the container and thus destroy it through evolution of

vapor or pyrochemical processes. Storage at great depths does not prevent radioactive fluids from penetrating into the ground water. The most promising method is to solidify all fluid radioactive matter, a possibility that is discussed in detail. Of special interest is the conversion of radioactive wastes into difficultly soluble precipitates, such as hydroxides, phosphates, etc. The best way to keep radioactive wastes on the spot is to deposit isotopes in the form of vitreous preparations of the smallest possible size. An analysis of the physicochemical fundamentals of producing such preparations is presented, and some specific features of the state and behavior of sealed-in radioactive fission fragments are discussed. The melting processes and also the formation of radioactive aerosols (which increases rapidly with temperature, especially above 1200°C) in the heat treatment of radioactive slimes are described. Fractional and X-ray structural analyses have shown that the melts obtained are inhomogeneous, i.e., the vitreous, amorphous preparation contains crystalline inclusions, particularly iron compounds, which are the principal carriers of radioactive fragments. Problems of leaching out and elution of radioactive matter by ground water, as well as self-heating
